**GLOBAL FOREST RESOURCES
ASSESSMENT UPDATE 2005**

**GUIDELINES FOR
COUNTRY REPORTING
TO FRA 2005**

ROME, 2004

The Forest Resources Assessment Programme

Forests are crucial for the well being of humanity. They provide foundations for life on earth through ecological functions, by regulating the climate and water resources and by serving as habitats for plants and animals. Forests also furnish a wide range of essential goods such as wood, food, fodder and medicines, in addition to opportunities for recreation, spiritual renewal and other services.

Today, forests are under pressure from increasing demands of land-based products and services, which frequently leads to the conversion or degradation of forests into unsustainable forms of land use. When forests are lost or severely degraded, their capacity to function as regulators of the environment is also lost, increasing flood and erosion hazards, reducing soil fertility and contributing to the loss of plant and animal life. As a result, the sustainable provision of goods and services from forests is jeopardized.

FAO, at the request of the member nations and the world community, regularly monitors the world's forests through the Forest Resources Assessment Programme. The Global Forest Resources Assessment 2000 (FRA 2000) reviewed the forest situation by the end of the millennium. FRA 2000 included country-level information based on existing forest inventory data, regional investigations of land-cover change processes and a number of global studies focusing on the interaction between people and forests. The FRA 2000 Main report is published in print and is available on the World Wide Web.

The Global Forest Resources Assessment update 2005 (FRA 2005) has been requested by the FAO Committee on Forestry in 2003. The FRA 2005 will use common thematic areas of the Criteria for Sustainable Forest Management as a reporting framework. FRA 2005 will also focus on the specific conditions and issues in each country.

The Forest Resources Assessment Programme is organized under the Forest Resources Division (FOR) at FAO headquarters in Rome. Contact person is:

1 Introduction

1.1 Background to FRA 2005

Global forest resources assessments have been carried out by FAO since 1947 (FAO, 1948), practically since FAO was formed. The mandate to carry out these assessments stems both from the basic statutes of FAO, and from the decision of the Committee on Forestry (COFO). Global assessment reports have been published at approximately ten year intervals. The latest of these reports, FRA 2000, was published in 2001 (FAO, 2001).

The Global Forest Resources Assessment Update for 2005, or FRA 2005, was requested by COFO 2001 and COFO 2003, where it was recommended that global forest resources assessments should: (a) be carried out at 5 year intervals, (b) be related to international forestry processes and (c) be implemented as a broad based assessment.

The main components of FRA 2005 are outlined below in order to give an overview of the entire process and to put the country reporting in a context. The following milestones are important for FRA 2005:

Milestone	Date	Comment
Global meeting of National Correspondents	Nov 2003	Training of National Correspondents and feedback on draft national reporting tables
Regional meeting of National Correspondents	May – Sep 2004	Review of country reports and technical assistance to National Correspondents
Deadline for country reports	Dec 2004	Country reports delivered to FAO according to specifications
COFO 2005	Mar 2005	Comprehensive progress report expected
UNFF5	May 2005	Comprehensive input on reporting processes expected
FRA 2005 launch	Oct 2005	New global data sets presented

1.2 Purpose of this report

This document contains guidelines for the National Correspondents (NC) on how to prepare the Country Reports to FRA 2005. It explains both the general methodology that should be applied and gives specific guidance for the completion of each of the 15 reporting tables. Together with the document “Specification of National Reporting Tables”, it constitutes the main reference documentation for the FRA 2005 reporting process. Complete country reports for five countries will also be made available on the FRA 2005 website. These pilot reports may serve as examples for the National Correspondents on how the country report should be elaborated.

2 Scope of Country Reporting to FRA 2005

The Global Forest Resources Assessment relies on information provided by the individual countries. FAO has established a framework for national reporting and conducts training and provides guidance to the national correspondents where needed in order to ensure that the information provided is complete and, as far as possible, compatible with the specifications of the national reporting tables.

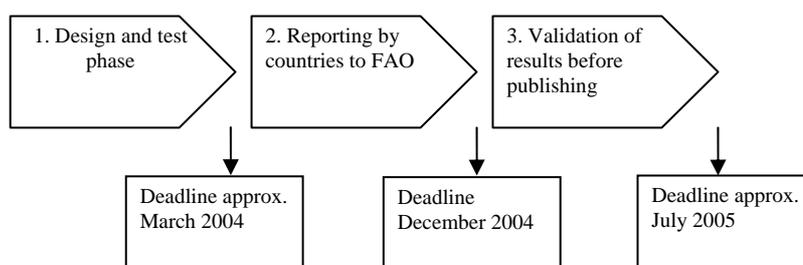

National Correspondents are requested to submit their Country Reports as FRA Working Papers¹ following a standardized format in order to facilitate their preparation and publication. A preformatted FRA Working Paper template to be used for the reporting is included in the documentation provided to the National Correspondents

The Country Reports should be submitted to FAO (preferably by e-mail or on diskette/CD-ROM) before the end of the year 2004. The FRA team will review the report and ask for clarifications and amendments if needed. Once the review is completed, countries will be asked for an official validation before publishing. This means that FAO does not require National Correspondents to obtain official approval before submitting the draft report. Country Reports should be written in either English, French or Spanish.

The country report will be divided into two separate parts:

- Standard country reporting. This report should be completed by all countries and follows a set of pre-defined reporting tables. It is of utmost importance to closely follow the specifications and guidelines provided by FAO as this will secure that data are as consistent as possible and follow a standard set of definitions, making it possible to compile information at regional and global level.
- Complementary country reporting by thematic areas. This is a voluntary report containing additional information considered important by individual countries, structured according to seven *common thematic areas* identified by the on-going regional and eco-regional processes on criteria and indicators for sustainable forest management.

The figure below presents the three main phases of the country reporting process and planned target dates. The country reporting process started with a design phase for developing, testing and evaluating the specifications and methodology for country reporting and data processing. The design phase is followed by a reporting, compilation and analytical phase. The third and final phase is the validation and delivery of national assessment reports.

¹FRA Working Papers is a series of documents elaborated within the FRA programme at FAO. The present document is an example of a FRA Working Paper

3 Methodology for country reporting to FRA 2005

3.1 The process

Validated, transparent and traceable country reports constitute the foundation of FRA 2005. All country information published by FAO should be traceable back to the original national data source. A standard methodology of documentation and reporting has been developed for this purpose.

The compilation of country reports following the proposed standard methodology will guarantee transparency in the reporting process and provide traceability of the country information to be published by FAO. Furthermore, this methodology will facilitate the reporting process and eventually reduce the reporting burden for countries.

The standard methodology for country reporting is a process that consists of three main steps, each of which renders an output that should be included in the country report. The figure below shows the process and the output from each step. Each step is also explained in more detail below.

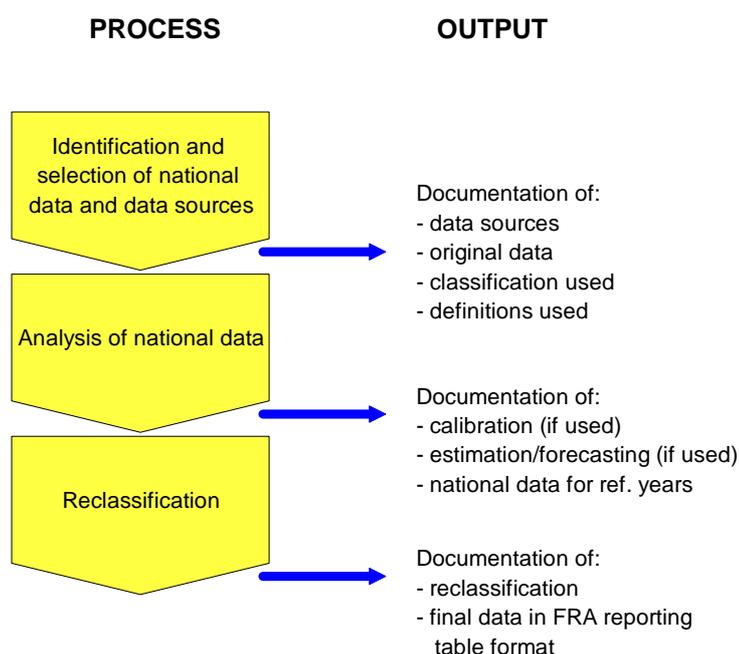

Figure 1. Outline of the standard methodology for country reporting to FRA 2005

Note that for each table, the National Correspondent should go through this process. Sometimes, minor deviations from the standard methodology might be necessary, but in such cases the deviations must be properly documented.

3.2 Step one – Identification and selection of national data sources

Based on the requirements of each specific table for FRA 2005, the country should identify all potentially useful data sources and evaluate the data sources according to content, completeness and quality. In the selection process it is important to choose data sources that use compatible sets of definitions and classification for different years in order to facilitate analysis of trends and estimation/forecasting of figures for the requested reference years. This means that select data sources should, if possible, allow for the establishment of a time series.

Once the selection of data sources has been made, these sources and corresponding data should be documented and included in the country report, following the structure outlined in the Template for Country Reports.

The documentation of each data source should cover at least the following:

- Full reference: Author(s), year of publication (if published), title and publisher.
- Reference year(s) for the data
- Quality assessment, according to the following classes:
 - High quality
 - Medium quality
 - Low quality
- Coverage (complete national coverage or partial coverage)
- Classification and definitions used, related to the particular reporting table

Documentation of national data can be presented in tabular form. Note that only the original data relevant for each specific reporting table and used for the further analysis need to be presented.

It is very important to report also when no data or information are available. More detailed guidelines on how to report when no data are available is found in chapter 4.2.

3.3 Step two – Analysis of National data

This step comprises two steps that may or may not be necessary to carry out, depending on the characteristics of available national data. These include:

- Calibration
- Estimation and forecasting

Calibration is used in order to make sure that reported area and area-related quantitative figures are consistent. For table T1, the total land area of a country report should match the official, reported land area according to FAOSTAT. Hence calibration may be needed in order to make these figures match. Similarly for tables T2 – T4, calibration may be needed to make total area of Forest and Other wooded land match the figures in table T1. For the other tables, calibration may sometimes be needed, particularly in cases when available data are partial or if the country believes that the national data considerably under- or overestimate the real values.

Example of calibration:

National category	1000 hectares
Forest	7 000
Bushland	3 000
Agriculture	3 000
Swamp	850
Urban land	100
Other	850
TOTAL land area	14 800

Calculating the calibration factor

Total land area according to FAOSTAT	15000
Calibration factor (= 15000/14800)	1.01351

Calibrated national data will then be as follows

National category	1000 hectares
Forest	7 095
Bushland	3 041
Agriculture	3 041
Swamp	861
Urban land	101
Other	861
TOTAL land area	15 000

Estimation and forecasting of values may be necessary in order to report national data for the FRA 2005 reference years (1990, 2000 and 2005). Estimation is the process of interpolation between observations and forecasting is extrapolation of values to the future.

In order to decide whether estimation and/or forecasting are necessary, the following general principles apply:

- If the country has data sources that provide observed data for the years 1990 and/or 2000, these data sets can be used directly without any estimation.
- If available data sets do not correspond to the requested reference years, estimation is required.
- Data for 2005 will always be forecasts.
- Forecasts may also be necessary for reference year 1990 and/or 2000 if the latest data set is older than the reference year.

The following examples show how estimation and forecasting can be carried out:

Example of Estimation using linear interpolation

Original data

National class	Growing stock (million m ³)	
	1988	2001
Forest	500	420
Bushland	300	330

Calculation of differences

Δx (2001-1988)	13	<i>(time between observations)</i>
Δy_{forest} (420-500)	-80	<i>(difference between observed values)</i>
Δy_{bush} (330-300)	30	<i>(difference between observed values)</i>
$\Delta y_{\text{forest}} / \Delta x$	-6.1538	<i>(difference per year)</i>
$\Delta y_{\text{bush}} / \Delta x$	2.3077	<i>(difference per year)</i>

Estimations

National class	Growing stock (million m ³)		
	1990	2000	
Forest	487.7	426.2	<i>(value 1988 + number of years after 1988 x $\Delta y_{\text{forest}} / \Delta x$)</i>
Bushland	304.6	327.7	<i>(value 1988 + number of years after 1988 x $\Delta y_{\text{bush}} / \Delta x$)</i>

Example of Forecasting using linear extrapolation

Original data

National class	Growing stock (million m ³)	
	1988	1997
Forest	500	460
Other wooded land	300	320

Calculation of differences

Δx (1997-1988)	9	<i>(time between observations)</i>
Δy_{forest} (460-500)	-40	<i>(difference between observed values)</i>
Δy_{owl} (320-300)	20	<i>(difference between observed values)</i>
$\Delta y_{\text{forest}} / \Delta x$	-4.4444	<i>(difference per year)</i>
$\Delta y_{\text{owl}} / \Delta x$	2.2222	<i>(difference per year)</i>

Forecasting

National class	Growing stock (million m ³)		
	2000	2005	
Forest	446.7	424.4	<i>(value 1997 + number of years after 1997 x $\Delta y_{\text{forest}} / \Delta x$)</i>
Other wooded land	326.7	337.8	<i>(value 1997 + number of years after 1997 x $\Delta y_{\text{owl}} / \Delta x$)</i>

Estimation and forecasting can obviously be made using other methods than linear inter- or extrapolation as shown in the example above. Sometimes trends are not linear, and curvilinear relationships must be applied. The NC has to choose a method that is appropriate considering the available data. In case of doubt, contact the FRA team for advice.

It is important to stress that estimation and forecasting is not only a question of making mathematical calculations. It is equally important to assess whether the estimated/forecasted

figures reflect reality. Many times there may be particular reasons why data from different years vary, and such variations do not necessary imply that there is a trend that can be used for estimation and forecasting.

From this second step, the output to the country report will be the following:

- Under sub-heading Calibration: A description of the calibration applied to data and formula used. If no calibration has been applied, this should be stated. If any other adjustments of original data have been made for the analysis (e.g. harmonization between different data sources), this should also be documented here.
- Under sub-heading Estimation and Forecasting: A description of how and for which years estimation and forecasting have been made or if original data have been used for some of the reference years. The formulas used must be included. This should also include an assessment of the reliability of estimated / forecasted values
- Documentation of national data for the reference years to be used as input for step three.

3.4 Step three – Reclassification of data

In order to make national data fit into the categories defined for FRA 2005, countries may have to reclassify the national data from the reference years. In some cases, when countries have National Forest Inventories that permit the direct calculation of data according to the FRA categories and definitions, the reclassification can be omitted.

Reclassification is usually carried out using a “reclassification matrix”, in which each national class is assigned a percentage that apply to each FRA category (see example below)

	FRA category 1	FRA category 2	FRA category 3	TOTAL
National class 1	70%	20%	10%	100%
National class 2	30%	50%	20%	100%

For each reporting table, the NC must decide whether reclassification is needed and if so, elaborate a reclassification matrix, taking into account the different national classes and the FRA categories according to the table specifications. This is often a rather subjective assessment, but if there is information available that supports this reclassification it should be documented.

Example of reclassification

In the reclassification matrix below for table T1, the national classes and their respective area are listed on the left hand side. On the right hand side the FRA categories are found. For each national class, the percentage that belongs to each FRA category is assessed, making sure that the sum equals 100%. In the particular case of table T1, the category "Other land with tree cover" (OLWTC) is a subcategory of "Other land" and included therein, hence it has been put outside the total, and the percentages in this column refers to the percentage of the area under "Other land".

Reclassification matrix

National classes	1000 ha	FRA Categories				OLWTC ²
		Forest	OWL ¹	Other land	TOTAL	
Productive forest land	15 000	100%			100%	
Swamp	3 000		30%	70%	100%	
Agriculture land	8 000			100%	100%	5%
National parks	3 500	65%	20%	15%	100%	
Urban land	500			100%	100%	10%
TOTAL	30 000	N/A	N/A	N/A	N/A	N/A

Result of reclassification

National classes	1000 ha	FRA Categories				OLWTC ²
		Forest	OWL ¹	Other land	TOTAL	
Productive forest land	15 000	15 000			15 000	
Swamp	3 000		900	2 100	3 000	
Agriculture land	8 000			8 000	8 000	400
National parks	3 500	2 275	700	525	3 500	
Urban land	500			500	500	50
TOTAL	30 000	17 275	1 600	11 125	30 000	450

1) OWL = Other wooded land

2) OLWTC = Other land with tree cover. This is a subcategory of "Other land", hence the percentage given in this reclassification matrix refers to the percentage of the area of "Other land" that has tree cover.

Reclassification should be applied for each reporting year. Many times, the same reclassification matrix can be used for all reporting years, but sometimes it might be necessary to make separate reclassification matrices for different years.

The output from the reclassification constitute the country data for the FRA reference years and categories and should be directly inserted in the relevant table in the country report.

Sometimes, national data from two different sources are using different definitions. In such cases, it may be necessary to perform a harmonization of national data before proceeding with the calculations, so that the national data follow a common standard regarding definitions. In some cases, where there are large differences between definitions in different national data sources, it might be better to reclassify each source directly to the FRA 2005 categories before proceeding with estimation and forecasting. However, this should be seen as an exception from the general rule that national classes should be maintained until the final reclassification step.

4 Guidelines for preparation of the National Reporting Tables

4.1 General aspects

Preparing the National Reporting Tables for FRA 2005 is an important task. Data provided in the country report will be compiled and published by FAO and will be widely used as a reference information regarding the world's forests. The reporting tables for FRA 2005 are comprehensive, and in many cases it will be necessary to form a multidisciplinary team in order to cover all aspects of the report. It may also take some time to identify and locate national data; it is therefore recommended that National Correspondents take the necessary steps for getting started with the process as soon as possible in order to not delay the submission of the country report.

4.2 How to report when data are weak or missing

Considering the scope of the national reporting tables, it will frequently happen that national data are either incomplete, weak or missing. The national correspondent has to decide, on a case to case basis, how to handle this, but as a general guidance, the following should be considered.

- Knowing that no national data are available is in itself very important information and should be documented in the country report.
- It is important to fill in all reporting tables even when national data are incomplete or non-existent. Where national data are missing or so weak that they cannot be used for generating requested information, countries may write "Insufficient Data (ID)" in corresponding fields of the reporting table. When Insufficient Data is reported, it should always be accompanied by a footnote that explains in what sense data are insufficient (e.g. missing, weak or incomplete, incompatible definitions, etc.).
- For some of the national reporting tables it is very important to get a complete coverage of country information (e.g. T1 and T5) and for these tables countries should provide their best possible estimate, even if this is a subjective expert estimate.

National correspondents are encouraged to contact the FRA team for advice if they are in doubt on how to proceed when available data do not allow for compiling requested information.

4.3 Table T1 – Extent of Forest and Other wooded land

This table is one of the most important tables for FRA 2005. Strong efforts should, therefore, be made to provide as reliable figures as possible. This table also constitutes the basis for the estimate of changes in global forest area, which always attracts much interest from the international community.

The FRA 2005 categories for this table are based on both land cover and land use. Countries may need to combine land cover and land use maps in order to provide information for this national reporting table. National forest inventory (NFI) data are good sources of information, if land cover and/or land use have been recorded.

For table T1, data sources are likely to include (but not restricted to) the following:

- Data and maps from vegetation mapping surveys
- Data and maps from land use planning
- Forest cover maps
- Agricultural maps
- National forest inventories

For each year of available data from selected data sources, the country should report relevant **original** figures from the data source. This might be done in one or several tables, depending on the complexity of the data. There is no predefined format for these tables, as data structures may vary between countries.

The countries must report areas on the four main categories (Forest, Other wooded land, Other land and Inland water). The sub-category “Other land with tree cover (OLWTC)” forms part of the category “Other land” and its area is thus included in “Other land” and should not be counted double when adding the areas. If countries have weak or missing information on this sub-category, they may choose to report Insufficient Data (ID) with a note that explains in what sense data was considered to be insufficient.

The area estimates for all years should be based on the current borders and area of the country. If borders and country area have changed during the period of reporting, figures should be calibrated to correspond to actual borders and area. If a country did not exist at the time of an earlier reporting year, Not Applicable (NA) should be reported for that year.

If there is no information on area of “Other land”, but good estimates of areas of “Forest” and “Other wooded land”, the area of “Other land” can be estimated by using Total land area and subtracting area of “Forest” and “Other wooded land”.

When compiling country data for table T1, it is important that the figure on total area for the country matches with the latest official UN statistics for country area as maintained by FAO (See FAOSTAT, <http://faostat.external.fao.org>.) Please check the respective area for your country according to FAOSTAT (see Appendix 2) and in case that area figures do not match, perform a calibration as explained in Chapter 3.3. For the calibration, it is generally recommended to use total land area as the basis. Area of inland water can then be taken directly from Appendix 2.

Appendix 1 contains a complete example of country reporting for table T1. Although it addresses some specific issues for table T1, it also serves as a general example for reporting.

If available national data do not match with the reference years requested by FRA, it is necessary to perform an estimation / forecasting of data according to the procedure set out in chapter 3.3. See also the example in Appendix 1.

If time series indicate trends that, according to the professional judgment of NC and other specialists taking part of the FRA reporting process, do not reflect the real situation, this must be documented in the country report. If necessary, the country may decide to make an adjustment of the estimated / forecasted data, but if so, this adjustment must be clearly documented and justified in the country report.

4.4 Table T2 – Ownership of Forest and Other wooded land

For table T2, data sources are likely to include (but not be restricted to) the following:

- NFI data, if information on ownership is collected
- National Forestry Statistics
- Register of land titles
- Maps on land ownership

Once the data sources are analyzed and selected, the country should document the existing national data, sources of data and definitions used.

Reclassification

It is important to recall that information on ownership only is requested for land that has been classified as Forest or Other wooded land. If available national data do not provide figures for Forest and Other wooded land respectively, a reclassification must be made.

The reclassification can be done in different ways, depending on available data. To ensure consistency in the country report regarding total area of Forest and Other wooded land, it is recommended to perform a reclassification so that the sum of the percentages for each of these two categories will be 100%. This may, however, result in totals for the ownership categories that do not completely match the original data.

Example: Reclassification of ownership categories

Basic data	
Data from Table T1:	
Forest	5000
Other wooded land	2000
Other land	6000
Total land area	13000
Inland water bodies	1000
Total area for country	14000
Figures from register of land titles	
Public land	4000
Private land	6000
Land without title	3000
Total land area	13000

In the basic data we see that from the total land area of 13000, 5000 is Forest and 2000 is Other wooded land. If the country information don't match area data from table T1, a calibration must be made.

For the following, we assume that no calibration was needed:

Percentages assigned in this example are entirely hypothetical. Note that the sum of the percentages for each row should be 100%

Reclassification matrix

	Public land	Private Land	Other ownersh.	Total
Forest	30%	50%	20%	100%
OWL	10%	75%	15%	100%

Result from reclassification

	Public land	Private Land	Other ownersh.	Total
Forest	1500	2500	1000	5000
OWL	200	1500	300	2000

Input to National reporting table (assume that example above refers to 1990)

FRA 2005 Categories	Area (1000 hectares)	
	Forest	OWL
	1990	1990
Private ownership	2 500	1 500
Public ownership	1 500	200
Other ownership	1 000	300
TOTAL	5 000	2 000

If a country reports area figures under the category “other ownership”, the country should specify what kind of ownership applies to this area.

In case it is difficult for a country to give good estimates for Forest and Other wooded land separately, while there are good figures for these two areas together, a country may report for these as a group. However, this must be clearly documented in the country report.

4.5 Table T3 – Designated functions of Forest and Other wooded land

This table is a complement to table T1, as it further breaks down the areas of Forest and Other wooded land according to their designated function. The term Designated function is defined as “the function or purpose assigned to a piece of land either by legal prescriptions or by the land owner/manager”.

Note that for FRA 2005 information is requested for areas with “Primary function” and for “Total area with function”. The areas which are recorded as “Primary functions” are exclusive and should only be counted once – consequently the total areas for Forest and Other wooded land should match the respective totals from table T1.

The “Total area with function” should report the total area that has a specific function, regardless of whether it is primary function or not. Areas that have more than one function will consequently be counted once for each function they are designated to provide. For example, the “Total area with function” for the category “conservation” will be calculated by assessing and adding all areas that are designated to provide the function “conservation”, independently of whether it is the designated primary function (see further the example below).

The complexity of this table makes it difficult to strictly follow the general methodology as outlined in chapter 3. Particularly, the reclassification is more complex. When applicable, the calibration, estimation and forecasting should be performed before making the reclassification.

When completing the table it is advisable to begin with compiling the area of “Primary function” (steps 1 to 3 in the example below). Normally the process will be carried out in several steps as further explained in the following example:

Example setting

For the example presented below the following information is available:

The total area of Forest and Other wooded land is 31 million hectares of which 25 million is Forest and 6 million hectares Other wooded land.

Of the 31 million hectares of Forest and Other wooded land it is assumed that there is a decree or management plans which stipulates that the primary use of 15 million hectares of Forest and OWL is for production of wood and non-wood forest products. It is further given that the total area of Forest and OWL which is legally protected or allocated in the management plan for protection is 5 million hectares. The remaining balance of 11 million hectares is not covered under legal decrees or management plans.

Example overview

Step 1 – Analysis and reclassification of areas with functions designated by legal or administrative prescriptions (in this example production area and protection area)

Step 2 – Analysis and classification of areas where no function has been designated by legal or administrative prescriptions

Step 3 – Compilation of areas with and without designated functions assigned by legal or administrative prescriptions

Step 4 – Assessment and classification of “Total area with function”

Step 5 – Compilation of total area with function

Note: Compile and report on existing national data

- Perform calibration, estimation and forecasting to reporting years when necessary
- Data for reporting years constitute the input for the following steps
- The steps below need to be repeated for each reporting year

Step 1: Analysis of areas with functions designated by legal or administrative prescriptions:

Let us assume that the production area is comprised of 80% forest and 20% OWL. Similarly, the protected area is comprised of 85% forest and 15% OWL.

Total **production area** 15 million ha.
 ...of which forest 80% or 12 million ha
 ... of which OWL 20% or 3 million ha

Total **protected area** 5 million ha.
 ... of which Forest 85% or 4.25 million ha
 ... of which OWL 15% or 0.75 million ha

Reclassification to FRA 2005 categories for “Primary designated function”

	Production		Protected areas	
	Forest	OWL	Forest	OWL
Area (1 000 ha)	12 000	3 000	4 250	750
Production	100%	100%		
Protection of soil and water ¹			20%	40%
Conservation of biodiversity ¹			80%	60%
Social services				
Multiple purpose				
No or unknown designation				
Total	100%	100%	100%	100%

¹The reclassification percentages assigned in this example are based on expert knowledge

The reclassification results in the following areas for “Primary designated functions”

	Production		Protected areas	
	Forest	OWL	Forest	OWL
Area (1 000 ha)	12 000	3 000	4 250	750
Production	12 000	3 000		
Protection of soil and water			850	300
Conservation of biodiversity			3 400	450
Social services				
Multiple purpose				
No or unknown designation				
Total	12 000	3 000	4 250	750

Step 2: Analysis of areas without a prescribed designated function

a) Total area of Forest without a prescribed designated function

Based on step one, the total area of Forest without prescribed designated function is 16.25 million hectares (12 mil. ha. Forest production area + 4.25 mil. ha. Forest protected area). The area of Forest where no function has been designated by legal or administrative prescriptions thus equals the total area of Forest¹ minus area designated with legal or administrative prescriptions.

In this example the area of Forest¹ is 25 mil. ha., the Forest area without any prescribed designated function is thus 8.75 mil. Ha. (25-16.25).

Assessment/classification of Forest area without any prescribed designated function

Primary designated function	Assessed percentage ²	Area (1000 ha)
Production	10%	875
Protection of soil and water	5%	437.5
Conservation of biodiversity	5%	437.5
Social Services	0	0
Multiple purpose	40%	3 500
No or unknown designation	40%	3 500
Total	100%	8 750

b) Total area of OWL without a prescribed designated function

Based on step one, the total area of OWL without a prescribed designated function is 3.75 million hectares (3 mil. ha. OWL production area + 0.75 mil. ha. OWL protected area). The area of OWL where no function has been designated by legal or administrative prescriptions thus equals the total area of OWL¹ minus area designated with legal or administrative prescriptions.

In this example the area of OWL¹ is 6 mil. ha. The OWL area without any prescribed designated function is thus 2.25 mil. Ha. (6-3.75).

Assessment/classification of OWL area without any prescribed designated function

Primary designated function	Assessed percentage ²	Area (1000 ha)
Production	10%	225
Protection of soil and water	0	0
Conservation of biodiversity	0	0
Social Services	10%	225
Multiple purpose	50%	1125
No or unknown designation	30%	675
Total	100%	2250

¹ Total Forest and OWL area should correspond with the figures given in National reporting table T1: Extent of Forest and Other wooded land

² In this example the assessed percentage of the total area without any prescribed designated function is based on expert knowledge.

Step 3 – Compile “Primary function” for the national reporting table by adding partial results from steps 1 and 2 above.

Primary function	Forest			OWL		
	Leg./Adm. designated	Not leg/adm. designated	Total area	Leg./Adm. designated	Not leg/adm. designated	Total area
Production	12 000	875	12 875	3 000	225	3 225
Prot. of soil and water	850	437.5	1 287.5	300		300
Cons. of biodiversity	3 400	437.5	3 837.5	450		450
Social services		0	0		225	225
Multiple purpose		3 500	3 500		1 125	1 125
No/unknown designat.		3 500	3 500		675	675
Total	16 250	8 750	25 000	3 750	2 250	6 000

The figures in bold are transferred to table T3 (if corresponding to the reference year).

Step 4 – Assess “Total area with function”

First, estimate for each total area of Primary function (output step 3), the percentage of the area that is designated to serve other functions than the one listed as the Primary function. This exercise will often be a subjective assessment.

For example, in the first row of the following table, estimations are made for the area where “Production” has been designated to be the primary function. The function “Production” covers of course 100% of this area but in addition about 20% of the area is also designated to provide “Protection of soil and water”, 30% of the area is also designated to provide “Conservation of biodiversity” and 30% of the area is also designated to serve the purpose of “Social services”.

a) Forest

Primary function	Area (1000 ha)	Percentage of area serving other functions			
		Prod.	Prot.	Cons.	Soc. serv.
Production	12 875	100%	20%	30%	30%
Prot. of soil and water	1 287.5		100%	60%	20%
Cons. of biodiversity	3 837.5		25%	100%	30%
Social services	0				100%
Multiple purpose	3 500	100%	100%	100%	50%

Note that the **primary designated function** by default is **100%**.

b) Other wooded land

Primary function	Area (1000 ha)	Percentage of area serving other functions			
		Prod.	Prot.	Cons.	Soc. serv.
Production	3 225	100%	10%	10%	50%
Prot. of soil and water	300		100%	50%	30%
Cons. of biodiversity	450		5%	100%	30%
Social services	225	40%		50%	100%
Multiple purpose	1 125	100%	30%	40%	40%

The estimated percentages in the above examples are based on expert knowledge.

Step 5 – Compile “Total area with function” for national reporting table T 3

The “total area with function” is calculated separately for Forest and OWL. The area is calculated by multiplying the total area of primary function (step 3) with the percentage of the specific function (step 4) that it is designated to provide. The product is then added for each specific function, for Forest and OWL respectively.

Detailed example of compilation of total Forest area with function “Production”

Primary function	Area Forest (1000ha) ¹	Production ²	
Production	12 875	100%	12 875
Protection of soil and water	1 287.5		
Conservation of biodiversity	3 837.5		
Social Services	0		
Multiple purpose	3 500	100%	3 500
			16 375

¹ Area total with primary designated function (step 3)

² Percentage of the area with primary function (step 4) which also is designated to serve a production function

Total area with Production function

Designated function	Total area with function	
	Forest	OWL
Production	16 375	4 440
Protection of soil and water	8 321.9	983
Conservation of biodiversity	11 972.5	1 485
Social services	8 771.3	2 513

4.6 Table T4 – Characteristics of Forest and Other wooded land

Table T4 intends to characterize the structure and composition of forest ecosystems and the degree of human impact on these. The division into different categories of characteristics involves a number of criteria, like visibility of human activities, presence of native and/or introduced species, regeneration methods, etc.

In the following figure, a matrix is presented to serve as reference for the classification used for FRA 2005. Some exceptions may occur as explained below the figure.

Human impact	No / Very little	Yes	Yes
Regeneration	<i>Natural regeneration</i>	<i>Natural regeneration</i>	<i>Assisted natural reg. / planting / seeding</i>
Native species	Primary	Modified Natural	Semi-Natural
Introduced species		Semi-Natural	Plantation

Native species

In the case of native species, the distinction between “Primary” and “Modified natural” is based on the degree of human impact. In order to classify a forest as “Primary” there should be no clearly visible indications/signs of human activities.

The distinction between “Modified natural” and “Semi-natural” is based on the regeneration method. If the forest/OWL is established by natural regeneration, or if it is not possible to tell whether it was assisted/planted/seeded, it should be classified as “Modified natural”. If it is clearly visible that the land was regenerated through assisted natural regeneration (soil treatment or planting/seeding) then it should be classified as “Semi-natural”.

Planted areas of native species, here listed as Semi-natural, may also in some circumstances be classified as “Plantations”. Such planted areas must then be characterized by even-aged stands of few species planted in a regular pattern. If countries decide to include areas with planted/seeded native species under “Plantations”, the criteria used to distinguish these areas from “Semi-natural” must be clearly documented.

Introduced species

In the case of introduced species, the general classification is as “Plantation”. However, if there are species that were introduced a long time ago, and there are stands of these species of subsequent generations that were naturally regenerated, these can be classified as “Semi-natural”.

For plantations, countries should also report on the type of plantations (productive or protective) depending on the purpose of these.

4.7 Table T5 – Growing stock

The growing stock is one of the basic and very important tables of the FRA 2005 report. In most cases it also constitutes the basis for the calculation of biomass and carbon stocks. Table T5 is closely related to tables T6, T7 and T10 and it is recommended that the estimations of growing stock needed for all these tables be undertaken simultaneously, as this may save time and efforts. By starting to compile information on growing stock by species, it will be easier to estimate biomass for table T6 as wood densities vary considerably between individual species. The information needed for T10 on the composition of growing stock will also come out directly when growing stock is compiled species-wise.

Data sources for growing stock estimates are usually forest inventories. Sometimes data from national forest inventories are available, but frequently inventory data do not completely represent the total area of forest and other wooded land respectively.

After selecting the data sources, countries should present the national data that constitute the basis for the estimates in table T5. Countries should clearly describe the national definition of growing stock and how it has been calculated, and also the geographical coverage of national data and how well the information represents the total area of forest and other wooded land.

Calculation of total growing stock

If a country has a national forest inventory, it should be possible to estimate the growing stock directly from the inventory data. This is the preferred method whenever possible.

If a country has only partial inventories, a decision has to be made on how the inventory data can be “expanded” to national estimates. One approach is to divide the total area of Forest and Other wooded land into broad classes of “forest types” or into eco-regions, and then use available inventory data to estimate per-hectare figures of growing stock for each of these broad classes. The totals for each class are then calculated and added together to obtain the requested estimates for Forest and Other wooded land (see example below).

In some cases, countries may have inventory data that does not directly include tree volume, but rather basal area or number of trees in different diameter classes. In those cases, countries will need to convert basal area or number of trees to volume. This can be done in several ways depending on the inventory data and any available complementary information, but it is difficult to provide any general guidance on how to perform these conversions. If in doubt, please contact the FRA team for advice. National correspondents must provide a description in the country report on how the calculations of growing stock were made and what volume equations or other factors were used.

Example: Growing stock estimates when only partial inventory data are available

The following area estimates are available (1000 hectares)

<i>Total Forest area:</i>	10 000
<i>Tropical moist forests:</i>	8 000
<i>Pine plantations</i>	1 500
<i>Eucalyptus plantations:</i>	500
<i>Total Area of OWL</i>	3 500

Inventory data give the following estimates:

<i>Tropical moist forests:</i>	95 m ³ /ha
<i>Pine plantations</i>	130 m ³ /ha
<i>Eucalyptus plantations:</i>	150 m ³ /ha
<i>Other wooded land</i>	20 m ³ /ha

Total growing stock can then be calculated as follows:

$$\begin{aligned} \text{Forest: } & (95 \times 8000) + (130 \times 1500) + (150 \times 500) \times 1000 = \underline{\mathbf{1\ 030\ million\ m^3}} \\ \text{OWL: } & (20 \times 3500) \times 1000 = \underline{\mathbf{70\ million\ m^3}} \end{aligned}$$

If it is difficult for a country to provide good estimates for Forest and Other wooded land separately, while there are good figures for these two areas together, a country may report for these as a group, as long as this is clearly documented in the country report.

Calculation of commercial growing stock

The commercial growing stock is a sub-set of the total growing stock. In order to calculate the commercial growing stock, the country must select a sub-set of data according to the following:

- Include only the areas where removal of wood is permitted and economically feasible
- Include only the commercial and potentially commercial species for domestic and international markets, given the current market conditions
- Include only the trees above the minimum diameter at breast height (DBH) for commercial trees, as defined by the country.

Once these selections have been made, inventory data can be used to obtain new estimates. In the case of partial inventories, the same procedure as outlined in the example above can be used.

Apart from these calculations, calibration and estimation/forecasting may also be needed in order to obtain figures for the requested reporting years and consistent with the areas of Forest and Other wooded land reported in table T1. These procedures are described in detail in chapter 3.

Finally, countries are requested to present some country-specific values as an appendix to the national reporting tables. It is very important to report these values as they are needed in order to harmonize data between countries for global reporting. These values are:

- Minimum diameter at breast height of trees included in growing stock (cm)
- Minimum diameter at the top end of stem for calculation of growing stock (cm)
- Minimum diameter of branches included in growing stock (cm)
- Minimum diameter at breast height of trees included in commercial growing stock (cm)
- Volume refers to “Above ground” or “Above stump”?
- Have any of the above thresholds changed since 1990 (yes/no), and if yes, then attach a separate note giving details of the change

4.8 Table T6 – Biomass stock

FRA 2005 and IPCC Good Practice Guidance

Data on biomass stock of Forest and Other wooded land are included in FRA 2005 since they respond to international reporting requirements for the climate convention and the Kyoto protocol, as well as for development of national policies.

For estimations of biomass and carbon, the FRA 2005 process relies on the methodological framework developed by the IPCC and documented in the *Good Practice Guidance for Land Use, Land-Use Change and Forestry* that will be published by IPCC during 2004. The methods described here and the default conversion factors for biomass and carbon as presented in tables in Appendix 5 are all based on the *Good Practice Guidance*. What is presented in this document for tables T6 and T7 is only a summary of those parts of the *Good Practice Guidance* that are relevant to FRA 2005.

Methodological aspects

For biomass calculation, irrespective of whether for above-ground biomass, below-ground biomass or dead wood biomass, there is a choice between the following different methods:

1. If national biomass functions and/or country-specific values of wood density (WD)², biomass expansion factors (BEF) and root-shoot biomass ratio (R) are available, using these should be the first choice
2. If country-specific biomass functions or values of any or all of WD, BEF and R are not available, regional or sub-regional functions or conversion factors should be used whenever available.
3. If neither country-specific, nor regional or sub-regional functions or values of WD, BEF and/or R are available, then the default values provided by the IPCC-GPG and reproduced in Appendix 5, tables 5.2 – 5.5 should be used.

If national biomass data are available directly from recent forest inventories, the data should be documented in the country report, and the standard procedure as described in chapter 3 should be followed.

When biomass is estimated based on growing stock data, countries should document the conversion factors used (WD, BEF, R), but the calculations can be simplified by using the estimated growing stock for the reference years from table T5 as input. Hence, no further calibration or reclassification is necessary.

² Wood density used for biomass calculations should always be the “Basic density”, which is oven-dry weight per unit of green volume. If country-specific wood densities are used, the country must make sure that these are “basic densities”.

Calculation of living biomass with general formulas and conversion factors

If no specific biomass functions are available, the following general formulas are used for calculating biomass from growing stock figures:

$$SB = GS \times WD \quad (1)$$

$$AGB = SB \times BEF \quad (2)$$

$$BGB = AGB \times R \quad (3)$$

Where

- SB = Stem biomass (tonnes)
- GS = Growing stock (volume) over bark (m³)
- WD = Wood Density (Dry weight / green volume expressed in tonnes/m³)
- AGB = Above-ground biomass (tonnes)
- BGB = Below-ground biomass (tonnes)
- BEF = Biomass expansion factor (Above ground biomass / stem biomass)
- R = Root-shoot ratio (Below-ground biomass / Above-ground biomass)

The starting point for the calculations is a list of growing stock (volume over bark) for individual species/species groups. This should be taken from the same set of national data as used for tables T5 and T10. Note that the sum of growing stock for all species should match the total growing stock in table T5.

The first step is to calculate the stem biomass. This is done by applying species-wise wood densities. If no national or local data on wood densities are available, default wood densities according to Tables 5.2 and 5.3 in Appendix 5 should be used (see example 1 below).

The second step is to calculate above-ground biomass. This is done by multiplying stem biomass with a biomass expansion factor (BEF). If no national or local data on biomass expansion factors are available, the default biomass expansion factors according to Table 5.4 in Appendix 5 should be used (see example 1 below).

The third step is to calculate below-ground biomass, multiplying the above-ground biomass by the root-shoot ratio. If no national or local data on root-shoot ratios are available, the default root-shoot ratios according to Table 5.5 in Appendix 5 can be used (see example 1 below).

Example 1: Calculation of living biomass

	Growing stock (million m ³)	Basic density (tonnes/m ³)	Stem biomass (million tonnes)	Biomass Exp.Fact	A.G biomass (million tonnes)	Root-Shoot Ratio	B.G biomass (million tonnes)
Species 1	500.00	0.45	225.00	1.35	303.75	0.35	106.31
Species 2	300.00	0.62	186.00	1.35	251.10	0.35	87.89
Species 3	200.00	0.55	110.00	1.22	134.20	0.35	46.97
Species 4	50.00	0.40	20.00	1.45	29.00	0.25	7.25
Species 5	30.00	0.51	15.30	1.35	20.66	0.35	7.23
TOTAL	1 080.00		556.30		738.71		255.65

Calculation of dead wood biomass

If the country has estimates of dead wood biomass based on country-specific data and/or conversion factors, these estimates should be reported. If no national data on dead wood biomass are available, countries may choose to either use the conversion factors provided by IPCC (Appendix 5, table 5.6) or to report Insufficient Data (ID) for dead wood biomass in the National Reporting Table. Note that the conversions factors provided by IPCC – dead-live ratios - are considered by IPCC to be very weak and they do not recommend to use them generally as default factors.

Biomass calculations for more than one year using weighted conversion factors

Like other data, biomass figures should be reported for 1990, 2000 and 2005. However, where the species composition of the growing stock has not changed significantly over the last 15 years, much time and effort can be saved by completing the species-wise calculation for one year, as indicated in the example above, and then calculate the weighted conversion factors for biomass as follows

$$\begin{aligned}WCF_{agb} &= AGB / GS \\WCF_{bgb} &= BGB / GS\end{aligned}$$

Where WCF_{agb} = weighted conversion factor for above-ground biomass
 WCF_{bgb} = weighted conversion factor for below-ground biomass
GS = Growing stock (volume) of all species
AGB = Above-ground biomass stock of all species
BGB = Below-ground biomass stock of all species

These weighted conversion factors can then be applied directly to the total growing stock figures for the other reporting years as follows:

$$\begin{aligned}AGB_y &= GS_y \times WCF_{agb} \\BGB_y &= GS_y \times WCF_{bgb}\end{aligned}$$

Where GS_y = Total growing stock for year y
 AGB_y = Total above-ground biomass for year y
 BGB_y = Total below-ground biomass for year y

Note that the calculations must be made separately for Forest and Other wooded land as species composition is different.

The countries should also document the threshold values used for fine roots and dead wood. If no specific threshold values have been defined (as when countries use the default conversion factors), the default values of 2 mm for fine roots and 10 cm for dead wood should be used.

Example 2: Using weighted conversion factors to calculate biomass for several years

Suppose that the figures from the table in the example above represent year 2000, and we have the following information from table T5:

FRA 2005 category	Volume (million m3 over bark)		
	Forest		
	1990	2000	2005
Growing Stock	1 200	1 080	1 020

First calculate the weighted conversion factors from the table in Example 1 above:

$$WCF_{agb} = AGB / GS = 738.71 / 1080 = 0.684$$

$$WCF_{bgb} = BGB / GS = 255.65 / 1080 = 0.237$$

Then apply these factors to the growing stock figures for 1990 and 2005 respectively

$$AGB_{1990} = 1200 \times 0.684 = 820.78$$

$$BGB_{1990} = 1200 \times 0.237 = 284.05$$

$$AGB_{2005} = 1020 \times 0.684 = 697.67$$

$$BGB_{2005} = 1020 \times 0.237 = 241.44$$

...and complete the national reporting table

FRA 2005 category	Biomass (million tonnes oven-dry weight)		
	Forest		
	1990	2000	2005
Above-ground biomass	820.8	738.7	697.7
Below-ground biomass	284.1	255.7	241.4
Total living biomass	1 104.8	994.4	939.1
Dead wood biomass ¹⁾	121.5	109.4	103.3
TOTAL	1 226.4	1 103.7	1 042.4

¹⁾ Dead wood calculated by using dead-live ratios (Appendix 5, Table 5.6)

4.9 Table T7 – Carbon stock

General methodological aspects

Carbon stock, like biomass stock, is estimated using the methodological framework provided by the IPCC Good Practice Guidance as explained in chapter 4.8.

The calculation of carbon stock will in most cases be based directly on the biomass data presented in table T6. However, if a country has made estimations of the carbon stock using other methods and obtained national data that provides more accurate estimates than by using the default conversion factors, these estimates as well as the methods and conversion factors used should be reported.

The following text and example illustrate the methodology of calculating carbon stock based on biomass data from table T6, using the default conversion factors and values provided by the IPCC-Good Practice Guidance (see Appendix 5, tables 5.7 and 5.8).

Carbon in living biomass

If national data on carbon content of living biomass are available, these should be used. If not, the carbon stock is calculated by multiplying the IPCC-GPG default value for carbon content of living biomass (50%) with the above-ground biomass and below-ground biomass respectively.

Carbon in dead wood

If data on dead wood biomass are available, the carbon stock can be calculated by multiplying the dead wood biomass with the IPCC-GPG default value for carbon content (50%); however national carbon content values should be used whenever possible. If a country has no data on dead wood biomass and carbon content, it may choose to either use the default factors provided by IPCC (Appendix 5, table 5.6) or report Insufficient Data (ID).

Carbon stock in litter

If national or regional data on carbon in litter are available, these should be reported. If no national or regional data are available, countries may choose to estimate carbon in litter by multiplying the IPCC-GPG default value per hectare with total area (see Appendix 5, table 5.7) or report Insufficient Data (ID).

Soil carbon

If national or regional data on soil carbon are available, these should be reported. Note that countries have to specify the soil depth that has been used for the soil carbon stock estimates. If no national or regional data are available, countries may choose to estimate soil carbon by multiplying the IPCC-GPG default value per hectare with total area (see Appendix 5, table 5.8) or report Insufficient Data (ID). If the IPCC-GPG default values are used, a soil depth of 30 cm should be reported.

Example: Calculation of Carbon Stock using the IPCC-GPG default factors.

In this example, data for biomass stock from Table T6 are used

FRA 2005 category	Biomass (million tonnes oven-dry weight)		
	Forest		
	1990	2000	2005
Above-ground biomass	820.8	738.7	697.7
Below-ground biomass	284.1	255.7	241.4
Total living biomass	1 104.8	994.4	939.1
Dead wood biomass ¹⁾	121.5	109.4	103.3
TOTAL	1 226.4	1 103.7	1 042.4

¹⁾ Dead wood calculated by using dead-live ratios (Appendix 5, Table 5.6)

Carbon stock of biomass for year 1990 can then be calculated as follows:

Carbon stock of above-ground biomass = $820.8 \times 50\% = 410.4$ million tonnes
 Carbon stock of below-ground biomass = $284.1 \times 50\% = 142.05$ million tonnes
 Carbon stock of dead wood biomass: = $121.5 \times 50\% = 60.75$ million tonnes

Furthermore, assume that the country in this example is located in the Tropical moist zone with evergreen forests and with the following soil conditions of the Forest area.

Forest	Area (1000 hectares)		
	1990	2000	2005
HAC soils	8 000	7 700	7 500
LAC soils	4 000	3 800	3 700
Sandy soils	3 000	3 000	2 800
Total	15 000	14 500	14 000

Carbon content of litter and soil can be found in the Appendix 5, tables 5.7 and 5.8 and are as follows for the above conditions:

Soil carbon content, HAC soils 65 tonnes C per ha
 Soil carbon content, LAC soils 47 tonnes C per ha
 Soil carbon content, Sandy soils 39 tonnes C per ha
 Litter carbon content 5.2 tonnes C per ha

Litter carbon for year 1990 can then be calculated as $5.2 \times 15000 / 1000 = 78$ million tonnes

Soil carbon must be calculated separately for each soil type, and for year 1990 will be:
 $[(8000 \times 65) + (4000 \times 47) + (3000 \times 39)] \times 1000 = 825$ million tonnes

This calculation must be repeated for each reporting year and also separately for Other wooded land.

4.10 Table T8 - Disturbances affecting health and vitality

Table T8 aims at providing information on areas affected by disturbances that have an impact on the health, vitality and productive capacity of Forest and Other wooded land. Three main categories are defined: areas disturbed by fire, by insects and by pests. There is also a category for “Other disturbances” where countries may report areas affected by drought, flooding, wind, acid rain, etc. If a country reports areas under “Other disturbances” the type(s) of disturbance should be specified in the report.

As these kinds of disturbances usually do not follow any regular pattern, there may be considerable variations over the years. The countries are therefore requested to report the annually affected area calculated as a 5-year average.

It may often be difficult to define whether a disturbance should be considered to have a significant impact on the health, vitality and/or productive capacity and thus be included in the reporting for table T8. Countries should be aware of this and report what criteria they have used for including and/or excluding certain disturbances.

In some cases, areas have been affected by different disturbances simultaneously, each of which is contributing to reduce the health and vitality of the ecosystem. For example there are areas affected by storm and insects, or flooding and diseases. In such cases the areas should be reported for each relevant disturbance, not only the dominating one. This implies that there is no reason to sum the areas in the reporting table.

As stated in the specification to the table, a disturbance should cover an area of at least 0.5 hectares and generate an impact that significantly affects the health and vitality of the forest in order to be included.

The data sources and availability of data for this table may vary between countries. If there are data available, although only partial, these data should be used as far as possible in order to provide the requested information. However, there will still be many countries where no information is available for any of the disturbance categories. In such cases, countries should report “Insufficient data”(ID).

4.11 Table T9 – Diversity of tree species

Table T9 on tree species diversity aims at giving an indicator of the biodiversity of the country and also to specify the number of tree species included in the IUCN red list of endangered species. Note that this table only requests data for year 2000.

First, the total number of identified native tree species should be reported. In countries with a large number of tree species, it will be necessary to collaborate with botanical institutions in order to obtain this number.

In this context it is important to emphasize the definition of the term “Tree”. For the FRA reporting, a tree is considered to be **“a woody perennial with a single main stem, or in the case of coppice with several stems, having a more or less definite crown”**. Bamboo’s and palms meeting these criteria are also considered as Trees. A tree should under normal conditions be able to reach the height of 5 m at maturity *in situ*, although this limit must be interpreted with flexibility.

Second, the number and a list of tree species included in the IUCN red list of endangered species should be reported for the following three categories:

- Critically endangered tree species
- Endangered tree species
- Vulnerable tree species

These categories (and some additional categories) were adopted by IUCN in 1994 and have since then become an internationally recognized standard for classifying endangered species. More information on the IUCN categories and their exact definitions can be found at the following website:

http://www.redlist.org/info/categories_criteria2001.html

Where national red lists are lacking or difficult to access, country-specific lists of endangered plants and animals can be accessed through the FRA website at the following address:³

<http://www.fao.org/forestry/site/20747/en>

Opening this website, the first thing to do is to select the country for which the species lists are to be compiled. Next, select “Critically endangered” in the menu to the left. In the window to the right will appear a list of species or a message that “No results were found.” Print and/or save the list and proceed to the “Endangered” and finally to the “Vulnerable”. Note that by using the categories under the heading “Redlist species – PLANTAE” you will restrict the search to plants and consequently get fewer species in the list. If you select the categories under the heading “Redlist species – All” the resulting list will also contain animals.

³ If there are any problems to compile the country specific lists from the indicated website, please contact the FRA team in order to get a hardcopy.

The lists compiled on this website include all plants. For the purpose of FRA 2005, countries should extract and compile a list of the tree species for each of the three reporting categories, to be included as an Appendix to the country report.

In the rightmost column of the list is an indication of the year when the species was included in the red list. Only species included before and up to year 2000 should be included in the report for FRA 2005.

Another data source for the number of redlisted tree species is the database of the World Conservation Monitoring Centre. Here, the number of tree species according to the IUCN categories are presented country-wise. No list of species names are currently available. This information is available at the UNEP-WCMC website:

http://www.unep-wcmc.org/trees/Background/country_stats.htm

4.12 Table T10 – Growing stock composition

In this table, countries are requested to report the growing stock of the ten most common species, regardless of their commercial status. This table should preferably be elaborated together with table T5 on growing stock.

Note that the figures in this table only apply to land classified as Forest in table T1.

The reference year for compiling the species list and the order of the species is year 2000. For comparison and trends, the values of growing stock for year 1990 should also be estimated. The totals of growing stock for year 1990 and 2000 should match corresponding values for forest in table T5.

Each species should be identified in the reporting table by both scientific name and common name. Countries may report on genera instead of species if their inventory data do not allow the distinction of individual species within certain species groups.

4.13 Table T11 – Wood removal

Table T11 deals with wood removal. Removal should not be confused with “consumption” or “harvesting / felling”. The consumption refers to national domestic production plus net imports and less exports. Harvesting/felling is the national production plus the quantity of the product left in the forest. The wood is considered to be removed when it leaves the forest, so wood harvested and stored on landings in the forest should not be considered as removed until it leaves the landing.

Note that wood removed during one year may originate from trees felled during several years and that the figures on wood removal requested for this table refer to volume over bark.

The reported figures for 1990 and 2000 should be based on an average of a five year period in order to take the annual variations into account. The figure for reference year 1990 will thus be based on the average of 1988 to 1992, and so on. If data are not available to produce five year averages for the reference year this should be documented along with information on how the value for the reference year(s) was reached. It could be the actual value for the reference year, if available, but preferably it should be an average value of two or more years (see section 3.3)

The value for reference year 2005 will be based on forecasting and will therefore not represent a five-year average. Values for the reference years 1990 and/or 2000 may also be based on forecasting if the most recent data are older than the reference year.

To estimate wood removal, there are two basic options. Each country should choose the option that their national experts consider will provide the most reliable estimates.

- Base the estimate on figures on wood removal already reported to international organizations (see e.g. Appendix 3).
- Direct estimation based on available national data, following the general methodology as outlined in chapter 3.

In any case, underlying national data should be documented and presented. That means that where data on wood removal were taken from Appendix 3, countries should report the national data that constituted the basis for the original report to FAO or ITTO.

Estimate wood removal from annual reports to international organizations

FAO, ITTO and EUROSTAT have during the last decades compiled annual statistics on wood removal. During the last five years, these institutions have distributed a Joint Forest Sector Questionnaire (JFSQ) where, among other things, countries are requested to report on wood removal. FAO maintains a global database on forest production, and here all the information on wood removal that countries historically have submitted can be found. Information on wood removal reported to FAO can be found in Appendix 3, where table 3.1 refers to removal of industrial wood and table 3.2 refers to removal of woodfuel.

In order to use the historically reported figures on wood removal as the basis for making the estimates for table T11, it should be kept in mind that there are two fundamental differences between what is to be reported to FRA 2005 and what countries are reporting for the JFSQ.

- FRA 2005 requests information on wood removal as volume over bark while the JFSQ and corresponding figures in Appendix 3 refer to volume under bark.
- FRA 2005 aims at identifying the long term trends and therefore asks for data as five-year averages, while the JFSQ requests annual data.

In order to use data from Appendix 3 to make estimations for table T11, the figures must be converted from volume under bark to volume over bark. This is done by applying a bark factor. Due to considerable regional variations, it is recommended that countries establish national bark factors and use these for the calculations. If no national bark factor can be established, a global default conversion factor of 1.15 can be used as a last resort for converting volume under bark to volume over bark (Source: IPCC Good Practice Guidance).

Making new estimates of wood removal from national data

If a country chooses to make new estimates, the general methodology as described in chapter 3 should be applied. The reason why earlier reported data are not used should then be explained.

National data sources are likely to include- (but not restricted to) any the following:

1. National forestry statistics
2. Trade statistics
3. Transport statistics
4. Statistics on wood consumption
 - In some countries where no or limited woodfuel data is available and woodfuel for subsistence represents a major wood removal component, the removal can be estimated on basis of population and studies on woodfuel consumption per capita.
 - Estimations can also be made by converting the volume of products produced in the country to the volume of roundwood required to produce that volume (the roundwood equivalent). (Source: FAO forestry statistics Series 171, FAO, 2001).

If needed, comment on units of reporting. The units of reporting must be comparable between reporting years. When conversion factors are used, these must be documented in the country report. Some conversion factors are listed in Appendix 5, table 5.1.

Example:

1. National statistics may give woodfuel figures in tonnes; the conversion factor from tonnes to round wood cubic meters should be documented. E.g. 1 metric ton woodfuel = 1.37931 cubic meter round wood. (Source: FAO forestry statistics Series 171, FAO 2001).
2. The volume of roundwood used in charcoal production, can be estimated by using a factor of 6.0 to convert from the weight (MT) of charcoal produced to the solid volume m³ of roundwood used in production (gives figure under bark). (Source FAO forestry series 171, FAO 2001). For further forest product measures etc., see Appendix 5, table 5.1

The unit of the final output (data for national reporting tables) for this table is wood removal in thousands of m³ round wood o.b. (measured over bark). It is important to document any conversion factors that have been used to convert any used national units to m³ round wood o.b.

Calibration may not be necessary unless only partial data are available and/or if there are apparent and documented reasons to believe that available data seriously over- or underestimate the “real” values and thus need calibration.

When national data are not directly available for the FRA 2005 categories, a reclassification is necessary. Below is an example of a reclassification matrix: Indicate the rationale behind the assignment of reclassification percentages.

	<i>Industrial Roundwood</i>	<i>Woodfuel</i>	<i>TOTAL</i>
<i>National class 1</i>			<i>100%</i>
<i>National class 2</i>			<i>100%</i>
<i>and so on...</i>			<i>100%</i>

This step is not necessary if national data are directly compatible with the FRA 2005 categories.

4.14 Table T12 – Value of wood removal

Table T12 is closely related to T11 and aims at showing the economic value of the removed wood.

Note that the value requested for this table should correspond to the market value of the wood at the border of the forest when it is at a roadside landing, loaded on a truck for road transport, or otherwise ready to be transported away from the forest.

The value should be reported in USD using the actual exchange rate for the reference year of the data. In Appendix 4 there is a list of historical exchange rates for most national currencies related to USD. The reported value should exclude taxes.

One method to estimate the value of wood removal, is to estimate a per unit value for industrial round wood and woodfuel and then multiply this value with the respective quantity as reported in table T11. In order to make this estimate, countries should be aware of the following:

- Each category (industrial roundwood and woodfuel) may be composed of different species or types of raw material that have different market values. In such a case, a weighted average value for the whole category must be estimated
- If there is no good information on market value at the border of the forest, a market value can usually be established further down the production chain (at industry gate, at consumer centres, etc.). In this case, transport costs from the forest to the place where the market value is assessed should be deducted. If any further processing has taken place before the value is assessed, processing costs should be deducted and necessary conversions must be made in order to account for processing losses.
- The assessment should also include wood that is removed for subsistence use with the value calculated on the basis of local market prices.

4.15 Table T13 – Non-wood forest products removal

Forests and other wooded lands provide a variety of products other than wood. These non-wood forest products are both socially and economically important. However, data on quantity and value of these products are often difficult to find.

The FRA 2005 report will include global statistics on production and value of non-wood forest products if sufficient information is available. In table T13 countries are therefore requested to provide information on the quantities of non-wood forest products removed, grouped in a number of categories (see table below). The reported figures should cover all removals, both for commercial and for non-commercial use.

Category	Reporting unit
<u>Plant products / raw material</u>	
1. Food	Mass (tonnes or kg)
2. Fodder	Mass (tonnes or kg)
3. Raw material for medicine and aromatic products	Mass (tonnes or kg)
4. Raw material for colorants and dyes	Mass (tonnes or kg)
5. Raw material for utensils, handicrafts & construction	Mass (tonnes or kg)
6. Ornamental plants	Mass (tonnes or kg)
7. Exudates	Mass (tonnes or kg)
8. Other plant products	Mass (tonnes or kg)
<u>Animal products / raw material</u>	
9. Living animals	Units
10. Hides, skins and trophies	Units
11. Wild honey and bee-wax	Mass (tonnes or kg)
12. Bush meat	Mass (tonnes or kg)
13. Raw material for medicine	Mass (tonnes or kg)
14. Raw material for colorants	Mass (tonnes or kg)
15. Other edible animal products	Mass (tonnes or kg)
16. Other non-edible animal products	Mass (tonnes or kg)

Data for most categories should be reported in units of mass (weight); only for the two categories “living animals” and “hides, skins and trophies” the report should refer to “units”. The country may choose to report mass (weight) in either tonnes or kg, furthermore there is an option in the reporting table to set a scale factor. Setting the scale factor to 1000 and units to tonnes, means that reported figures are in 1000 tonnes.

If existing national data are reported in terms of volume instead of mass, data should be converted to mass and it must be well documented in the report how this conversion has been done and what conversion factors have been used.

To take annual variations into account, the figures reported should be an average of a five year period (for reference year 1990 an average of the period 1988 to 1992 and for reference year 2000 an average of the period 1998 to 2002). The figures for 2005 will be forecasts.

Only removals from Forest and Other wooded land should be reported. If a country only has figures referring to all types of land for a certain product, it is necessary to either estimate and document the share that correspond to Forest / OWL or report the available figures and document clearly that it applies to all types of land.

Finally, countries are requested to report in an Appendix, the most important species used for each product category. This information is very important in order to improve reporting for future assessments.

If a country does not have any documented information on a specific non-wood forest product category, but there is a general agreement among local experts on rough figures of removals, the country may choose to report these, stating clearly that the data source is “subjective assessment of local experts”. Otherwise, the country may choose to report Insufficient Data (ID).

4.16 Table T14 – Value of non-wood forest products removal

Table T14 is closely related to T13 and aims at showing the economic value of the removed non-wood forest products.

The values to be reported refer to the market value at the site of collection or forest border. If values are obtained from a point further down the production chain, transport costs and possible handling and/or processing costs should be deducted. In case that the NWFP are removed for subsistence use, the value should be calculated based on the local market value.

The value should be reported in USD using the actual exchange rate for the reporting year. In Appendix 4 there is a list of historical exchange rates for most national currencies related to USD. The value should be reported excluding taxes.

The procedure to calculate the value, is the same as for wood in table T12. First, the per unit value of each category is calculated, taking into account that it might be necessary to estimate a weighted average for the category if the different products that make up the category have considerably different market prices. Then, this average is multiplied with the quantity as reported in table T13.

Alternatively, values are estimated for each individual product and then added together to give consolidated figures for the predefined categories.

4.17 Table T15 – Employment in forestry activities

Reporting on employment in forestry activities is new within the FRA reporting context. It responds to the request by COFO and member countries that FAO should facilitate access to information on a wider range of goods and services provided by forests and woodlands.

In this table, countries are requested to report on employment in forestry activities related to the primary production of goods and services.

Note that employment refers to work performed or services rendered in exchange for wage or salary under some kind of contract or agreement. Voluntary work, as well as unpaid work performed by individuals or communities for subsistence or commercial purposes are not included (see further the definitions in the document Specification of National Reporting Tables).

Data reported should preferably be based on national statistics on labor and employment. If partial statistics exist, these can be calibrated to apply to national level. If no national information is available, countries may report Insufficient Data (ID).

5 Guidelines for preparation of country reports on thematic areas

The reports on thematic areas are voluntary reporting tables on issues considered important by each individual country and where recent information on national level is available. As these tables may vary between countries, there are no predefined formats, but it is recommended that the information be organized in the report according to the common themes of the Criteria & Indicators processes. The thematic reporting should also take into consideration the importance of identifying trends, so when possible the thematic reports should follow the same reporting years as the standard reporting tables. It is also important to describe data sources, methodology, etc. in a similar way as for the standard reporting tables, so that the figures presented in the report are traceable back to original data.

Countries are also reporting to other international processes, conventions and fora on issues related to forestry. Important tables from these reports can also be reproduced in the FRA 2005 country report under Thematic Reporting, making the country report more comprehensive.

The UNFF session for 2005 will make a global evaluation of the progress in implementing sustainable forest management. Countries may wish to take the opportunity of including complementary information that show how the country is proceeding towards sustainable forest management in the FRA 2005 thematic reports.

Thematic reporting may, for example, cover issues such as:

- Ownership and access rights
- Area under management plans
- Area of forest under a forest certification scheme
- Etc.

These are of course only examples and the countries should feel free to include whatever theme they may consider important in the report.

6 How to use the template

A template file has been distributed to the National Correspondents in order to facilitate the compilation of the country report. The Country Report Template contains the basic structure of the country report, following a standardized format for publication as a FRA working paper. This template provides one chapter for each table and, under each table, a number of sub-headings. The sub-headings follow the methodology explained in this document.

It is important that all countries use this template, and provide information under each sub-heading as appropriate. The following may serve as guide as to what should be included under each sub-heading:

FRA 2005 Categories and definitions

The FRA 2005 categories and definitions are included in the beginning of each table to make the Country Report self-explaining without access to other FRA documents.

National Data Sources

Document clearly and concisely all data sources that have been selected and used for the specific FRA 2005 reporting table. Assign a quality rating to the data sources. Comment on any problems encountered in finding relevant data sources. If no data sources have been found that meet the requirements, this should be noted.

National Classification and Definitions

Document clearly and concisely all the classifications and definitions used in the national data sources that have been selected and used for the FRA 2005 reporting process. Comment on any problems or incompatibilities in classification and definitions.

Original National Data

Present in tabular form the data available from the selected data sources. Comment on any inconsistencies or other problems that may affect further analysis.

Calibration

If calibration of area related data has been performed (see chapter 3.3), indicate the calibration factor used. Calibration may also be used if the data presented do not reflect the situation at national level. In such a case, indicate how the calibration has been performed and for what reason.

Estimation and Forecasting

If estimation and/or forecasting has been performed in order to report data for the FRA 2005 reference years (1990, 2000, 2005), indicate how the estimation / forecasting has been performed. Comment on any problems

Reclassification into FRA 2005 Classes

When national data are not directly available for the FRA 2005 categories, a reclassification is necessary. The reclassification matrix should be presented here, and the rationale behind the assignment of reclassification percentages should be indicated.

Data for National reporting table TXX

Insert a table with data according to the template from the document “Specification of National Reporting Tables”.

Comments to National reporting table TXX

Use, if necessary, to give any particular comments on the data presented in the national reporting table.

7 Contact information for technical support

The FRA team of professional staff is available to answer questions and give technical support to countries during the reporting process. There is also an electronic discussion forum open for everybody, where questions can be posted, and where the discussions held are visible for everybody. The discussion forum is constantly monitored by the FRA team. The discussion forum can be accessed on the following link:

<http://www.fao.org/forestry/site/21330/en>

Countries are also welcome to take direct contact with the professional staff at the FRA Secretariat and with the Forestry Officers at the FAO regional and sub-regional offices in matters related to FRA 2005.

APPENDICES

Appendix 1 – Complete example of country reporting for table T1

Appendix 2 – List of UN official country areas

Appendix 3 – Roundwood production officially reported to FAO

Appendix 4 – Historical exchange rates

Appendix 5 – Conversion factors for volume, biomass and carbon

Table 5.1	General weight and volume conversion factors
Table 5.2	Basic wood densities – Boreal and temperate species
Table 5.3	Basic wood densities – Tropical species
Table 5.4	Default biomass expansion factors
Table 5.5	Default root-shoot biomass ratios
Table 5.6	Default dead-live biomass ratios
Table 5.7	Default values for carbon in litter
Table 5.8	Default values for soil carbon

Appendix 1 – Example of country reporting for table T1

The following example illustrates country reporting for table T1, following the structure proposed in the Template for Country Reporting. The example shows how the standard methodology can be applied when completing a reporting table. The national data in this example are entirely hypothetical and does not correspond to any specific country.

2. Table T1 - Extent of Forest and Other wooded land

2.1. FRA 2005 Categories and definitions

Category	Definition
Forest	Land spanning more than 0.5 hectares with trees higher than 5 meters and a canopy cover of more than 10 percent, or trees able to reach these thresholds <i>in situ</i> . It does not include land that is predominantly under agricultural or urban land use.
Other wooded Land	Land not classified as “Forest”, spanning more than 0.5 hectares; with trees higher than 5 meters and a canopy cover of 5-10 percent, or trees able to reach these thresholds <i>in situ</i> ; or with a combined cover of shrubs, bushes and trees above 10 percent. It does not include land that is predominantly under agricultural or urban land use.
Other land	All land that is not classified as “Forest” or “Other Wooded Land”.
Other land with tree cover (Subordinated to “Other land”)	Land classified as “Other land”, spanning more than 0.5 hectares with a canopy cover of more than 10 percent of trees able to reach a height of 5 meters at maturity.
Inland water bodies	Inland water bodies generally include major rivers, lakes and water reservoirs.

2.2. National data

2.2.1. National data sources

References to sources of information	Quality (H/M/L)	Variable	Years	Additional comments
a) Smith, B 1988. <i>National Pine forest and mangrove inventory</i> . Hypothetical country	M ¹	Land use, Forest cover, Growing stock	1986	National inventory of pine and mangrove forests covering the whole country, using remote sensing and field sample plots.

¹ Assessed as Medium quality “M”. The source document only provides information for two of the three main forest classes.

² Assessed as Low quality “L”. Reference is based on expert knowledge not supported by field information.

2.2.2. National classifications and definitions

National class	Definition
Coppice forest	The coppice hardwood forests are native forests of various hardwood species such as buttonwood, mahogany, gum elemi, rat wood, black ebony, brazilletto, horseflesh and red cedar.
Pine forest	Pine forests of <i>Pinus caribaea</i> .
Wetlands	Land that includes the mangrove forest ecosystems which occurs predominantly on the shores of the country covering the 80 percent of the total wetland. It also includes swamps, and low lands.
Forest land	Includes all land classified as Coppice forest, Pine forest and Wetlands.
Non-forest land	Includes all land not classified as forest land.

Information on threshold values (canopy cover, tree height, etc.) used for defining Forest and Other wooded land in FRA 2005 is not defined in national definitions. For that reason, based on local expert advice, it is assumed that national definitions of "pine forests", "coppice forest" and "mangrove forest" correspond with the FRA 2005 thresholds for classifying them as "Forest".

2.2.3. Original national data

National class	1986 1000 ha	1992 1000 ha
Pine forest	200,000	185,000
Coppice forest ¹	600,000	600,000
Wetland	100,000	100,000
Total forest land	900,000	885,000
Non-forest land ²	100,000	115,000
Total land area	1,000,000	1,000,000

¹) Estimated from original data as: Total forest land area - area of pine forest – area of wetland

²) Estimated from original data as: Total land area – Total forest land area

Note that national data does not provide any assessment of the area of Coppice forest. Additionally, the inventory of the mangrove forests (Smith, 1988) showed that of the wetlands, 80% of the area was covered by mangrove forests and the remaining 20% were swamps.

2.3. Analysis and processing of national data

2.3.1. Calibration

Source	Total land area (1000 hectares)
National data	1,000,000
FAOSTAT	1,000,000

There is no need to perform calibration since the national land area data matches the FAOSTAT land area.

2.3.2. Estimation and forecasting

National classes	1986	1992	1990 ²	2000 ²	2005 ²
	1000 ha	1000 ha	1000 ha	1000 ha	1000 ha
Pine forest	200 000	185 000	190 000	165 000	152 500
Coppice forest ¹	600 000	600 000	600 000	600 000	600 000
Wetlands ¹	100 000	100 000	100 000	100 000	100 000
Total forest land area	900 000	885 000	890 000	865 000	852 500
Non-forest land	100 000	115 000	110 000	135 000	147 500
Total land area	1 000 000	1 000 000	1 000 000	1 000 000	1 000 000

¹ There has been no change in the categories of coppice forest and wetland forest as these are under protection since the year 1977. (Forestry Department, 2003)

² Data for the year 1990 was estimated using linear interpolation of the data from 1986 and 1992. Similarly, data for years 2000 and 2005 were forecasted using the same linear trend.

The estimated and forecasted figures are considered by local expertise to well describe the current state and trends.

2.4. Reclassification into FRA 2005 classes

National classes	FRA 2005 Categories				
	Forest	OWL	Other Land	Total	OLWTC
Pine forest ¹	100%			100%	NDA ²
Coppice forest ¹	100%			100%	NDA ²
Wetlands ³	80%		20%	100%	NDA ²
Non-forest land ¹		20%	80%	100%	NDA ²

¹ Assessment based on expert knowledge

² No data or knowledge available for making assessment of area under "Other land with tree cover"

³ Inventory of mangrove forest (Smith, 1988)

2.5. Data for national reporting table

FRA 2005 categories	Area 1000 hectares		
	1990	2000	2005
Forest	870 000	845 000	832 500
Other wooded land	22 000	27 000	29 500
Other land	108 000	128 000	138 000
.... of which with tree cover	NDA ¹	NDA ¹	NDA ¹
Total land area	1 000 000	1 000 000	1 000 000
Inland water bodies ²	5 000	5 000	5 000
Total area for country	1 005 000	1 005 000	1 005 000

¹ No data available

² Data on area of inland water bodies from FAOSTAT

2.6. Comments to National reporting table T1

The main weakness in the existing national data is the lack of information on the Coppice forest. Another weakness is that there is no national information available on Other land, and particularly the part of Other land that has a tree cover.

*The IMF distinguishes between the following three categories of exchange rates:

Market Rates (MR), Largely determined by market forces;

Official Rates (OR), determined by government authorities; and

Principal Rates (PR), for countries maintaining multiple exchange rates arrangements.

The preference is always market rates, only when these are not available other rates are used.

Appendix 5 – Table 5.1. General weight and volume conversion factors

Units	Metric Equivalents
1 Inch	= 25.4 millimetres
1 Square foot	= 0.0929 square metre
1 Cubic foot	= 0.02832 square metre
1 Short ton	= 0.9072 metric ton
1 Long ton	= 1.016 metric ton

Table Approximate Equivalents for Forest Measures

Product and Unit	Cubic Meters (u.b.)	Cubic Feet (u.b.)
<i>Sawlogs & veneer logs</i>	<i>Solid volume without bark</i>	
1000 board/super feet	4.53	160
<i>Pulpwood round and split</i>		
1 stere	0.72	25.4
1 cord	2.55	90
<i>Woodfuel</i>		
1 stere	0.65	23
1 cord	2.12	74.9
1000 stacked cubic feet	18.41	650

Table Weight and Volume

Product	Kg/CUM			CUM/MT		
	G	C	NC	G	C	NC
Woodfuel, incl. wood for charcoal	725	625	750	1.38	1.60	1.33
Wood charcoal	167					
Sawlogs and Veneer logs						
Tropical			730			1.37
Other		700	800		1.43	1.25
Pulpwood, round and split	675	650	750	1.48	1.54	1.33
Other industrial roundwood	750	700	800	1.33	1.43	1.25
Sawnwood		550	700		1.82	1.43
Veneer sheets	750			1.33		
Plywood	650			1.54		
Particle board	650			1.54		
Hard board	950			1.053		
Medium density fibreboard (MDF)				2		
Insulating board	250			4		

Note: G = General; C = Coniferous; NC = Non-coniferous

APPENDIX 5 - TABLE 5.4
DEFAULT VALUES OF BIOMASS EXPANSION FACTORS (BEFs)
(BEF to be used in connection with growing stock biomass data)

SOURCE: IPCC GOOD PRACTICE GUIDANCE FOR LULUCF – TABLE 3A.1.10

Climatic zone	Forest type	Minimum dbh (cm)	BEF (overbark) to be used in connection to growing stock biomass data
Boreal	Conifers	0-8.0	1.35 (1.15-3.8)
	Broadleaf	0-8.0	1.3 (1.15-4.2)
Temperate	Conifers: Spruce-fir	0-12.5	1.3 (1.15-4.2)
	Pines	0-12.5	1.3 (1.15-3.4)
	Broadleaf	0-12.5	1.4 (1.15-3.2)
Tropical	Pines	10.0	1.3 (1.2-4.0)
	Broadleaf	10.0	3.4 (2.0-9.0)

Note: BEFs given here represent averages for average growing stock or age, the upper limit of the range represents young forests or forests with low growing stock; lower limits of the range approximate mature forests or those with high growing stock. The values apply to growing stock biomass (dry weight) including bark and for given minimum diameter at breast height; Minimum top diameters and treatment of branches is unspecified. Result is above-ground tree biomass.

DEFAULT REFERENCE (UNDER NATIVE VEGETATION) SOIL ORGANIC C STOCKS (SOC_{REF})
(tonnes C per ha for 0-30 cm depth)

SOURCE: IPCC GOOD PRACTICE GUIDANCE FOR LULUCF – TABLE 3.2.4

Region	HAC soils ¹	LAC soils ²	Sandy soils ³	Spodic soils ⁴	Volcanic soils ⁵	Wetlands soils ⁶
Boreal	68	NA	10 [#]	117	20 [#]	146
Cold temperate, dry	50	33	34	NA	20 [#]	87
Cold temperate, moist	95	85	71	115	130	
Warm temperate, dry	38	24	19	NA	70 [#]	88
Warm temperate, moist	88	63	34	NA	80	
Tropical, dry	38	35	31	NA	50 [#]	86
Tropical, moist	65	47	39	NA	70 [#]	
Tropical, wet	44	60	66	NA	130 [#]	

Note: Data are derived from soil databases described by Jobbagy and Jackson (2000) and Bernoux *et al.* (2002). Mean stocks are shown. A default error estimate of 95% (expressed as 2X standard deviations as percent of the mean are assumed for soil-climate types. NA denotes 'not applicable' because these soils do not normally occur in some climate zones.

indicates where no data were available and default values from 96 GL were retained.

¹ Soils with high activity clay (HAC) minerals are lightly to moderately weathered soils, which are dominated by 2:1 silicate clay minerals (in the World Reference Base for Soil Resources (WRB) classification these include Leptosols, Vertisols, Kastanozems, Chernozems, Phaeozems, Luvisols, Alisols, Albeluvisols, Solonetz, Calcisols, Gypsisols, Umbrisols, Cambisols, Regosols; in USDA classification includes Mollisols, Vertisols, high-base status Alfisols, Aridisols, Inceptisols).

² Soils with low activity clay (LAC) minerals are highly weathered soils, dominated by 1:1 clay minerals and amorphous iron and aluminium oxides (in WRB classification includes Acrisols, Lixisols, Nitisols, Ferralsols, Durisols; in USDA classification includes Ultisols, Oxisols, acidic Alfisols).

³ Includes all soils (regardless of taxonomic classification) having > 70% sand and < 8% clay, based on standard textural analyses (in WRB classification includes Arenosols; in USDA classification includes Psamments).

⁴ Soils exhibiting strong podzolization (in WRB classification includes Podzols; in USDA classification Spodosols)

⁵ Soils derived from volcanic ash with allophanic mineralogy (in WRB classification Andosols; in USDA classification Andisols)

⁶ Soils with restricted drainage leading to periodic flooding and anaerobic conditions (in WRB classification Gleysols; in USDA classification Aquic suborders).
